

# Internet Technology

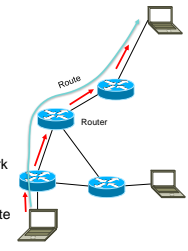

## 07. Network Layer

Paul Krzyzanowski  
Rutgers University  
Spring 2016

CS 352 © 2013-2016 Paul Krzyzanowski 1

## Network Layer

- **Transport Layer (Layer 4)**
  - Application-to-application communication
- **Network Layer (Layer 3)**
  - Host-to-host communication
- **Route**
  - The path that a packet takes through the network
- **Routing**
  - The process of moving the packet along the route
- **Forwarding**
  - Transferring a packet from an incoming link to an outgoing link
- **Router**
  - The device that forwards packets (datagrams)

CS 352 © 2013-2016 Paul Krzyzanowski 2

## Forwarding vs. Routing

- **Routing**
  - Responsibility over the path
  - **Routing algorithms** figure out the path a packet should take
- **Forwarding**
  - A router consults a **forwarding table**
  - Examines data in a packets header & uses the table to determine the outgoing link for the packet
  - Routing algorithms configure forwarding tables
- **Switches vs. Routers**
  - **Packet switches:** transfer data between links based on link layer data (e.g., Ethernet)
  - **Routers:** transfer data between links based on network layer data (e.g., IP)

CS 352 © 2013-2016 Paul Krzyzanowski 3

## Network service models: our wish list

What would we like from a network?

- Guaranteed delivery (no loss)
- Bounded (maximum) delay
- In-order packet delivery
- Guaranteed constant or minimum bandwidth
- Maximum jitter
  - Jitter = variation in latency
- Endpoint authentication & encrypted delivery

March 23, 2016 CS 352 © 2013-2016 Paul Krzyzanowski 4

## Network service models: what do we get?

- IP gives us none of this
  - **Best-effort** = no guarantees on delivery, delay, order
- Other network architectures provide some of these items
  - E.g., ATM (Asynchronous Transfer Mode)
  - ATM CBR (Constant Bit Rate)
    - Connection setup specifies bandwidth
    - Network provides constraints on jitter and packet loss
    - Network guarantees in-order delivery
  - ATM ABR (Available Bit Rate)
    - In-order delivery
    - Guaranteed minimum bandwidth but higher rates if resources available
    - Feedback to sender if congestion is present

March 23, 2016 CS 352 © 2013-2016 Paul Krzyzanowski 5

## Virtual Circuit vs. Datagram Networks

- **Virtual Circuit (VC) Networks**
  - Connection service at the network layer
  - All routers in the path are involved in the connection
- **Datagram Networks**
  - Connectionless service at the network layer
  - Connection-oriented service provided at the transport layer
    - Only end systems are involved
    - Routers are oblivious

*IP is a datagram network*

March 23, 2016 CS 352 © 2013-2016 Paul Krzyzanowski 6

### Virtual Circuit Networks

- Connection setup**
  - Set up route based on destination address
  - Each router commits resources
  - Each router builds entries in its forwarding table
    - Routers maintain **connection state information**
- Communication**
  - Each packet contains a VC#
  - Forwarding table determines the next link and VC#
  - Destination address *not* needed on each packet; just the VC#
- Teardown**
  - Clear connection from forwarding table on each router

Incoming Interface	Incoming VC #	Outgoing Interface	Outgoing VC #
1	12	2	83
1	9	2	101
2	4	1	151

Forwarding Table

March 23, 2016 CS 352 © 2013-2016 Paul Krzyzanowski 7

### Datagram Networks

- Packet identified with the destination address
- No setup; routers maintain no state information
- Routers
  - Use the destination address to forward the packet
  - Forwarding table maps destination address to output link
- IP addresses are 32 bits
  - We can't have a forwarding table with  $2^{32}$  (4,294,967,296) entries!
  - Match a range of addresses by matching a prefix

192.168.\*.\* = Rutgers

longest prefix matching rule { 15.[32-47].\*.\* = HP

15.\*.\*.\* = HP

Prefix	Outgoing Interface
1000 0000 0000 0110	2
0000 0111 0010	3
0000 0111	1

Forwarding Table = Routing Table

CS 352 © 2013-2016 Paul Krzyzanowski 8

## The Router

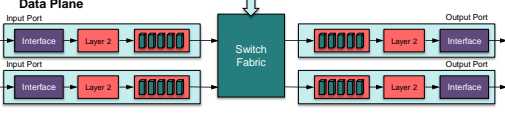

CS 352 © 2013-2016 Paul Krzyzanowski 9

### Router Architecture

**Control Plane**

System Tasks  
Routing Processor

**Data Plane**

**Control Plane: Routing & Management**

- Run routing protocols & maintain routing tables
- User command interface
- Accounting
- ICMP
- Queue management

**Data Plane: Packet Forwarding**

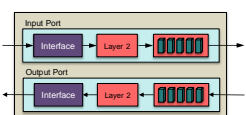

- Layer 1: Retime & regenerate signal
- Layer 2: Rewrite header and checksum
- Layer 3: Look up, queue, decrement TTL, regenerate checksum, forward to output port

*Note: a port on a router refers to the input & output interfaces, not a transport-layer port*

CS 352 © 2013-2016 Paul Krzyzanowski 10

### Router Architecture: line cards

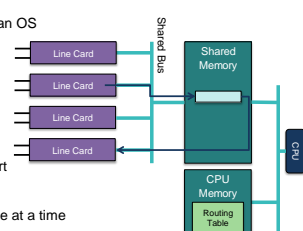

A **line card** is responsible for I/O on a specific interface

CS 352 © 2013-2016 Paul Krzyzanowski 11

### Shared Memory - Conventional

- Ports
  - Function as I/O devices in an OS
- Packet arrival
  - CPU interrupt
  - Copied to memory
- Routing
  - CPU determines route
  - Copies packet to output port
- Limitation
  - Only one memory read/write at a time
  - CPU & bus can be bottlenecks

CS 352 © 2013-2016 Paul Krzyzanowski 12

### Shared Memory – Distributed CPUs

- CPU & copy of routing table in each line card
- Lookup and data copy to output port done by line card
- Limitation
  - Only one memory read/write at a time
  - Bus can be a bottleneck

The diagram shows four line cards, each with its own CPU. These are connected to a central shared bus. On the right side of the bus is a shared memory block containing a 'Master Routing Table' and 'CPU Memory'. A 'CPU' block is also shown on the far right, connected to the bus. A dashed red line indicates a path from a line card CPU to the shared memory.

CS 352 © 2013-2016 Paul Krzyzanowski

13

### Shared Bus – No Shared Memory

- No shared memory
- Bus used to copy packets directly from one port to another
- Limitation
  - Shared bus can be a bottleneck

The diagram shows four line cards, each with its own CPU. They are connected to a shared bus. To the right of the bus is a separate block containing 'CPU Memory' and a 'Routing Table'. A 'CPU' block is also shown on the far right, connected to the bus. A dashed red line indicates a path from a line card CPU to the routing table.

CS 352 © 2013-2016 Paul Krzyzanowski

14

### Non-shared Memory – Crossbar Data Path

- NxN crossbar switching fabric
- One port can move a packet to another port without blocking other ports
- Multiple switching fabrics can be used to route packets to the same port
- Verdict
  - Fastest solution
  - \$\$\$

The diagram shows four line cards, each with its own CPU. These are connected to a central 'Crossbar Switch' represented by a grid. To the right of the switch is a 'CPU' block. Below the switch is a block containing 'CPU Memory' and a 'Routing Table'. A dashed red line indicates a path from a line card CPU to the routing table.

CS 352 © 2013-2016 Paul Krzyzanowski

15

### Output Port Queuing

- If there's a queue at an output port
  - A packet scheduler chooses one packet for transmission
  - This can be simple first-come-first-served (FCFS)
  - ... or take other factors into account (source, destination, protocol, service level)
- If the output port queue is full
  - We have packet loss
  - A router can decide which packet to drop
  - Active Queue Management (AQM) algorithms: decide which packets to drop

CS 352 © 2013-2016 Paul Krzyzanowski

16

### Input Port Queuing

- If packets arrive faster than they could be switched
  - They need to be queued at input ports
  - If multiple queues have a packet for the same output port
    - Only one will be switched at a time
    - The others will be blocked ... and the packets behind them will be blocked too!
    - Head-of-line blocking
- If the queue overflows
  - We have packet loss

CS 352 © 2013-2016 Paul Krzyzanowski

17

### Head-of-line blocking

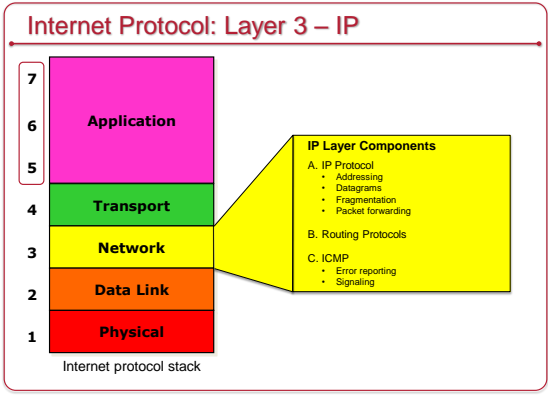

The diagram shows three input ports on the left, each with an 'Interface' and 'Layer 2' block. Each has a queue of packets. A 'Switch Fabric' is in the center. On the right, there are three output ports, each with a 'Layer 2' block and 'Interface'. A packet in the top queue is highlighted in yellow. An arrow points from this packet to the switch fabric. A label says 'If this packet has to wait'. Another label says 'Then these packets have to wait' with arrows pointing to the other two queues. This illustrates how a delay in one queue can block packets in other queues.

CS 352 © 2013-2016 Paul Krzyzanowski

18

# Internet Protocol

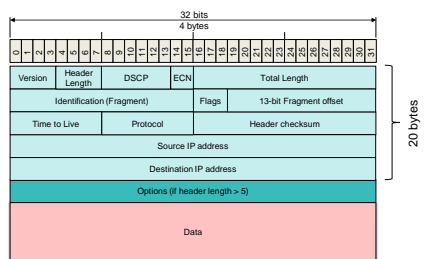

CS 352 © 2013-2016 Paul Krzyzanowski 19

March 23, 2016 CS 352 © 2013-2016 Paul Krzyzanowski 20

## IP Datagram Structure

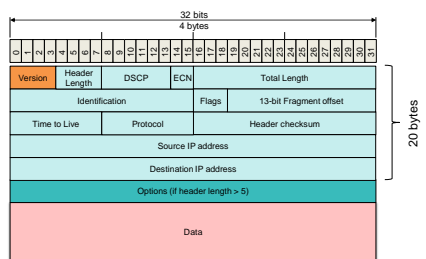

- 20 byte fixed part
- Variable-size options

CS 352 © 2013-2016 Paul Krzyzanowski 21

## IP Datagram: Version

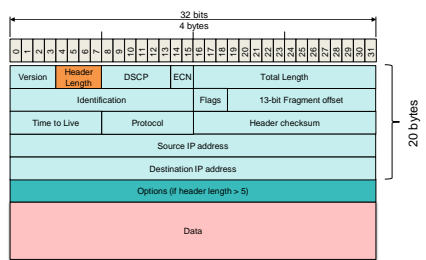

- 4-bit identification of the protocol used: 4 = IPv4

CS 352 © 2013-2016 Paul Krzyzanowski 22

## IP Datagram: Header Length

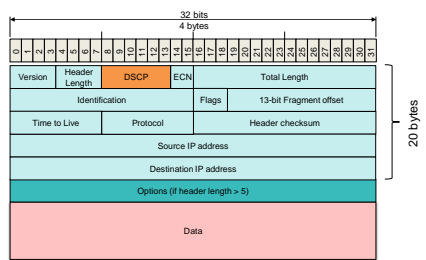

- 4-bit header length (in # of 32-bit words)
- IP packets usually have no options, so this is usually 5

CS 352 © 2013-2016 Paul Krzyzanowski 23

## IP Datagram: DSCP

- Differentiated Services Control Point
- Identifies class of service for QoS aware routers (e.g., VoIP)

CS 352 © 2013-2016 Paul Krzyzanowski 24

### IP Datagram: ECN

- Explicit Congestion Notifications
  - Routers normally do not inform endpoints of congestion
  - ECN is an optional feature to allow them to do so

The diagram shows a 20-byte IP header structure. The ECN field (bits 14-15) is highlighted in orange. The fields are: Version (4 bits), Header Length (4 bits), DSCP (6 bits), ECN (2 bits), Total Length (16 bits), Identification (16 bits), Flags (3 bits), 13-bit Fragment offset (13 bits), Time to Live (8 bits), Protocol (8 bits), and Header checksum (16 bits).

CS 352 © 2013-2016 Paul Krzyzanowski 25

### IP Datagram: Total Length

- 16-bit value of the entire datagram (including the 20-byte IP header)

The diagram shows a 20-byte IP header structure. The Total Length field (bits 16-31) is highlighted in orange. The fields are: Version (4 bits), Header Length (4 bits), DSCP (6 bits), ECN (2 bits), Total Length (16 bits), Identification (16 bits), Flags (3 bits), 13-bit Fragment offset (13 bits), Time to Live (8 bits), Protocol (8 bits), and Header checksum (16 bits).

CS 352 © 2013-2016 Paul Krzyzanowski 26

### IP Datagram: Fragmentation

- Fragmentation
  - **Identification:** Identifies fragment of an original datagram
  - **Flags:** control fragmentation or identify if there are more fragments
  - **Fragment offset:** offset of fragment relative to original data

The diagram shows a 20-byte IP header structure. The Identification (bits 16-31), Flags (bits 3-5), and 13-bit Fragment offset (bits 6-19) fields are highlighted in orange. The fields are: Version (4 bits), Header Length (4 bits), DSCP (6 bits), ECN (2 bits), Total Length (16 bits), Identification (16 bits), Flags (3 bits), 13-bit Fragment offset (13 bits), Time to Live (8 bits), Protocol (8 bits), and Header checksum (16 bits).

CS 352 © 2013-2016 Paul Krzyzanowski 27

### IP Datagram: Time-To-Live

- Hop count: decremented by 1 each time the datagram hits a router
  - If TTL == 0, discard the packet
  - Keeps packets from circulating indefinitely (common TTL = 60..64)

The diagram shows a 20-byte IP header structure. The Time to Live field (bits 8-15) is highlighted in orange. The fields are: Version (4 bits), Header Length (4 bits), DSCP (6 bits), ECN (2 bits), Total Length (16 bits), Identification (16 bits), Flags (3 bits), 13-bit Fragment offset (13 bits), Time to Live (8 bits), Protocol (8 bits), and Header checksum (16 bits).

CS 352 © 2013-2016 Paul Krzyzanowski 28

### IP Datagram: Protocol

- Identifies the protocol in the data portion
  - TCP = 6, UDP = 17
  - IANA assigns these numbers

The diagram shows a 20-byte IP header structure. The Protocol field (bits 16-23) is highlighted in orange. The fields are: Version (4 bits), Header Length (4 bits), DSCP (6 bits), ECN (2 bits), Total Length (16 bits), Identification (16 bits), Flags (3 bits), 13-bit Fragment offset (13 bits), Time to Live (8 bits), Protocol (8 bits), and Header checksum (16 bits).

CS 352 © 2013-2016 Paul Krzyzanowski 29

### IP Datagram: Header Checksum

- 1s complement checksum of the header
  - Router discards packet if corrupt
  - Must be recalculated by the router since TTL (& maybe options) change

The diagram shows a 20-byte IP header structure. The Header checksum field (bits 16-31) is highlighted in orange. The fields are: Version (4 bits), Header Length (4 bits), DSCP (6 bits), ECN (2 bits), Total Length (16 bits), Identification (16 bits), Flags (3 bits), 13-bit Fragment offset (13 bits), Time to Live (8 bits), Protocol (8 bits), and Header checksum (16 bits).

CS 352 © 2013-2016 Paul Krzyzanowski 30

### IP Datagram: Source & Destination

- Identifies source and destination IP addresses

CS 352 © 2013-2016 Paul Krzyzanowski

31

### IP Datagram: Options

- Extensions to the header – *rarely used*
- Options include: route to destination, record of route, IP timestamp

CS 352 © 2013-2016 Paul Krzyzanowski

32

### IP Fragmentation & Reassembly

- Remember MTU (Maximum Transmission Unit)?
  - Maximum size of payload that a link layer frame can carry
  - This limits the size of an IP datagram (and hence a TCP or UDP segment)
- What if a router needs to forward a packet that is larger than that link's MTU?
  - Break up the datagram into two or more **fragments**
  - Each fragment is a separate IP datagram
  - IP layer at the end system needs to **reassemble** the fragments before passing the data to the transport layer

CS 352 © 2013-2016 Paul Krzyzanowski

33

### IP Fragmentation

- When an IP datagram is first created
  - Sender creates an ID number for each datagram (usually value of a counter)
  - DF** bit ("Don't Fragment") set to 0: fragmenting is allowed
- When a router needs to fragment a datagram
  - Each fragment contains the same ID #, source address, destination address
  - Fragment offset**
    - Identifies offset of the fragment relative to the original datagram in 8-byte blocks
    - First datagram Offset = 0
  - All fragments except for the last one have the **MF** ("More Fragments") bit set

CS 352 © 2013-2016 Paul Krzyzanowski

34

### IP Fragmentation

- Example: send 4,000 byte datagram
  - 20 bytes IP header + 3980 bytes data
- Outbound link at router has a 1500-byte MTU

CS 352 © 2013-2016 Paul Krzyzanowski

35

### IP Reassembly

- Identification**
  - Receiver knows a packet is a fragment if MF is 1 and/or Fragment Offset is not 0
- Matching & Sequencing**
  - Identification field is used to match fragments from the same datagram
  - Offsets identify the sequence of fragments
- Size of original**
  - When the receiver gets the last fragment (MF=0, Offset != 0)
  - It knows the size of the datagram (offsetx8)+length
- Giving up**
  - If any parts are missing within a time limit, discard the packet
  - Linux: `/proc/sys/net/ipv4/icmp_time` (default 30 seconds)
- Once reassembled, pass to protocol that services this datagram

CS 352 © 2013-2016 Paul Krzyzanowski

36

# IP Addressing

CS 352 © 2013-2016 Paul Krzyzanowski 37

# IP Addressing

- IPv4 address: 32 bits expressed in dotted-decimal notation
  - www.rutgers.edu = 0x80064489 = 128.6.68.137
- Each interface needs to have an IP address
  - E.g., each link on a router has an address
  - If your laptop is connected via Ethernet and 802.11, you have 2 IP addresses
  - Every interface at a router has its own address

CS 352 © 2013-2016 Paul Krzyzanowski 38

# Route Aggregation: Subnets

- IP address = 32 bits =  $2^{32}$  addresses
  - But addresses cannot be assigned randomly
  - Otherwise routing tables would have to be  $2^{32}$  entries long!
  - ... and maintaining them would be a nightmare
- Instead, assign groups of adjacent addresses to an organization
 

- www.rutgers.edu = 128.6.68.137
  - All hosts in Rutgers start with 128.6
  - First 16 bits of the IP address identify a host at Rutgers
  - Routers need to know how to route to just 128.6 instead of all 65,536 ( $2^{16}$ ) possible addresses
- Route aggregation = use one prefix to advertise routes to multiple devices or networks

CS 352 © 2013-2016 Paul Krzyzanowski 39

# Subnets

- Subnet (= subnetwork = network)
  - Group of IP addresses sharing a common prefix ( $n$  high-order bits)
  - A logical network connected to a router (LAN or collection of LANs)
- Rutgers subnet = 128.6.0.0/16
  - CIDR notation (Classless Inter-Domain Routing)
  - A/N:  $N$  most significant (leftmost) bits of address

www.rutgers.edu = 128.6.68.137

10000000 00000110 01000100 10001001

Network number                      Host number

CS 352 © 2013-2016 Paul Krzyzanowski 40

# Subnet Mask

- A subnet mask (or netmask)
  - A bit mask with 1s in the network number position
  - Address & netmask → strips away host bits
  - Address & ~netmask → strips away network bits
- For Rutgers, the netmask is
 

16 bits – network                      16 bits – host

11111111 11111111 00000000 00000000

255.255.0.0
- For a 221.2.1.0/26 network, the netmask is
 

26 bits – network                      6 bits – host

11111111 11111111 11111111 11000000

255.255.255.192

CS 352 © 2013-2016 Paul Krzyzanowski 41

# How are IP addresses assigned?

From Lecture 3: DNS

IP addresses are distributed hierarchically

- Internet Assigned Numbers Authority (IANA) at the top
  - IANA is currently run by ICANN
    - Internet Corporation for Assigned Names and Numbers

IANA

Regional Internet Registries (RIR): AfriNIC, APNIC, ARIN, LACNIC, RIPE NCC

Allocate blocks of addresses to ISPs

ISPs

Your computer (or Internet gateway)

- We will look at NAT later
- Permanent (static) or temporary (dynamic)

RIR Map

- AfriNIC
- APNIC
- ARIN
- LACNIC
- RIPE NCC

CS 352 © 2013-2016 Paul Krzyzanowski 42

### Address allocation: it's a hierarchy

Routing, everything to 200.23.16.0/20 goes here

ISP gets 200.23.16.0/20

Org A, Org B, Org C

200.23.16.0/23, 200.23.18.0/23, 200.23.20.0/23

Subnetting, dividing a network into smaller networks, can be repeated at each level of the hierarchy

CS 352 © 2013-2016 Paul Krzyzanowski

43

### Subnet Mask Example Within Rutgers

- Rutgers = 128.6.0.0 – netmask is
   
 $11111111\ 11111111\ 00000000\ 00000000$ 
  
 255.255.0.0
   
 IP address range: 128.6.0.0 – 128.6.255.255
- Rutgers iLab systems are on a subnet within Rutgers
   
 $11111111\ 11111111\ 11111111\ 10000000$ 
  
 255.255.255.128
   
 IP address range: 128.6.13.128 – 128.6.13.255

CS 352 © 2013-2016 Paul Krzyzanowski

44

### Special addresses

- Network address:** all host bits 0
  - Rarely, if ever, used
  - Rutgers = 128.6.0.0
- Limited broadcast address:** all bits 1
  - Broadcast address for *this network*, the local network.
  - Datagrams are not forwarded by routers to other networks
- Directed broadcast address:** all host bits 1
  - All hosts on the specified subnet get datagrams sent to this address
  - Routers may or may not forward broadcasts (no for outside an organization)
  - Rutgers iLab systems = 128.6.13.255 (network=128.6.13.128)
- Loopback address:** 127.0.0.1 = localhost
  - Communicate with your own device
  - Uses the loopback network interface

CS 352 © 2013-2016 Paul Krzyzanowski

45

### Host Configuration

- How do you assign an address to a host?
  - Manually, configure the device with its
    - IP address
    - Subnet mask, so it knows what addresses are local
    - Gateway: default address for non-local addresses not in a routing table
      - Router that connects the LAN to another network
    - DNS server addresses(s), so it can look up addresses
  - Automatically, via the Dynamic Host Configuration Protocol (DHCP)

CS 352 © 2013-2016 Paul Krzyzanowski

46

### Dynamic Host Configuration Protocol

- Protocol for client to get an IP address and network parameters
- It has to work before the client has a valid address on the network!
  - Use IP broadcasts
- DHCP server must be running on the same network link (LAN)
  - Else each link must run a *DHCP Relay Agent* that forwards the request to a DHCP server

CS 352 © 2013-2016 Paul Krzyzanowski

47

### DHCP: Three mechanisms for allocation

- Automatic allocation**
  - DHCP assigns an permanent IP address to a client
  - This association remains fixed until the administrator changes it
- Dynamic allocation**
  - DHCP assigns an IP address to a client for a limited period of time
  - Allows automatic reuse of an address that is no longer needed by the client
- Manual allocation**
  - A client IP address is assigned by the network administrator

CS 352 © 2013-2016 Paul Krzyzanowski

48

### DHCP: The Protocol

**Discover**

**Client**

*Client broadcasts DHCP Discover*

- Client sends a limited broadcast *DHCP Discover* UDP message to port 67
- Contains random transaction identifier

**Request**

*Client broadcasts DHCP Request*

- Sends back a DHCP message with a copy of the parameters
- This performs *selection* (if multiple offers), *confirmation of data*, *extension of lease*

**Offer**

**Server**

*Server responds with an offer*

- Server sends a limited broadcast *DHCP Offer* UDP message to port 68
- Response contains
  - Matching transaction identifier
  - Proposed IP address
  - Subnet mask
  - Lease time

**ACK**

**Server**

*Server sends DHCPACK*

- Sends configuration parameters, including committed IP address

D-O-R-A

CS 352 © 2013-2016 Paul Krzyzanowski

49

### NAT: Network Address Translation

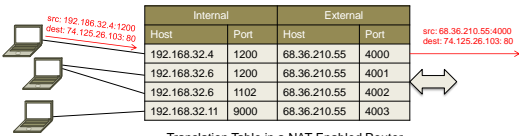

- Every device on the Internet needs an IP address
  - Every address has to be unique
    - ... otherwise, how do you address a host?
- IP addresses are not plentiful
  - Does an organization with 10,000 IP hosts really need 10,000 addresses?

CS 352 © 2013-2016 Paul Krzyzanowski

50

### NAT: Network Address Translation

- Private IP address space in the organization
- One external IP address
- NAT Translation Table**
  - Map source address:port in outgoing IP requests to a unique external address:port
  - Inverse mapping for incoming requests
- A NAT-enabled router looks like a single device with one IP address

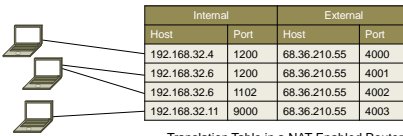

Translation Table in a NAT-Enabled Router

CS 352 © 2013-2016 Paul Krzyzanowski

51

### NAT: Network Address Translation

- NAT requires a router to look at the transport layer!
  - Source port (outgoing) & destination port (incoming) changes
  - TCP/UDP checksum recomputed

Translation Table in a NAT-Enabled Router

CS 352 © 2013-2016 Paul Krzyzanowski

52

### NAT: Private Addresses

- We cannot use IP addresses of valid external hosts locally
  - ... how will we distinguish local vs. external hosts?
- RFC 1918: Address Allocation for Private Internets
  - Defines unregistered, non-routable addresses for internal networks

Address Range	# addresses	CIDR block
10.0.0.0 – 10.255.255.255	16,777,216	10.0.0.0/8
172.16.0.0 – 172.31.255.255	1,048,576	172.16.0.0/12
192.168.0.0 – 192.168.255.255	65,536	192.168.0.0/16

CS 352 © 2013-2016 Paul Krzyzanowski

53

### NAT variants

- Static NAT**
  - One-to-one mapping between internal and external addresses
- Dynamic NAT**
  - Maps an unregistered (internal) IP address to one of several registered IP addresses
- Overloading, or Port Address Translation (PAT)**
  - A form of dynamic NAT that maps multiple internal IP addresses to a single registered address by using different ports

CS 352 © 2013-2016 Paul Krzyzanowski

54

### Advantages of NAT

- Internal address space can be much larger than the addresses allocated by the ISP
- No need to change internal addresses if ISP changes your address
- Enhanced security
  - A computer on an external network cannot contact an internal computer
    - Unless the internal computer initiated the communication
    - But can only contact the computer on that specific port (this is where active mode FTP had problems)

CS 352 © 2013-2016 Paul Krzyzanowski

55

### ICMP

CS 352 © 2013-2016 Paul Krzyzanowski

56

### Internet Control Message Protocol (ICMP)

- Network-layer protocol to allow hosts & routers to communicate network-related information
- ICMP information is carried as IP payload

CS 352 © 2013-2016 Paul Krzyzanowski

57

### ICMP Segment Structure

- Variable-size segment; 8-byte minimum
- Type: command or status report ID
- Code: status code for the type
- Checksum: Checksum from ICMP header & data
- Rest of header: depends on type
  - Error reports contain the IP header & first 8 bytes of original datagram's data

### Some ICMP Message Types

Type	Description
0	Echo reply (ping)
3	Destination unreachable
4	Source quench
5	Redirect message
8	Echo request
9	Router advertisement
10	Router solicitation
11	TTL exceeded
12	Bad IP header
13	Timestamp
14	Timestamp reply
17	Address mask request
18	Address mask reply

59

### Ping program

- Get a network ping (echo) from a requested host
  - Test network reachability
  - Measure round-trip time
  - Optionally specify packet size
- Request/response protocol
  - Ping Client
    - Create socket (AF\_INET, SOCK\_RAW, IPPROTO\_ICMP)
    - Set IP header fields & ICMP header fields
    - Send it to a destination via `sendto()`
    - Wait for a response from the destination address via `recvfrom()`

60

### Ping program

- Request
  - Send ICMP type=8 (echo request), code 0 (no options to echo)

Type = 8	Code = 0	Checksum
Identifier	Sequence number	
Timestamp	Data	
Data		

Associate replies with requests

- Reply
  - Destination responds back with an ICMP type=0 (echo reply), code=0

Type = 0	Code = 0	Checksum
Same identifier	Same sequence number	
same timestamp	Same data	
Same data		

CS 352 © 2013-2016 Paul Krzyzanowski 61

### Traceroute program

- Traceroute – trace a route to a specific host
  - Send a series of UDP segments with a bogus destination port
    - 33434 to 33534 on Linux systems
  - First IP datagram has TTL=1
  - Second IP datagram has TTL=2, and so on
  - Keep a timer for each datagram sent
- At a router
  - When the TTL expires, a router sends an ICMP warning message
  - Type 11, code 0 = TTL expired
  - ICMP message includes the name of the router and its IP address
- At the final destination
  - The destination sends an ICMP warning message
  - Type 3 code 3 = Destination port unreachable

### IPv6

- We've been rapidly using up IPv4 addresses ever more rapidly
  - Growth of the web
  - Always-on IP devices
  - Set-top boxes and phones
  - Inefficient network allocation
- We dealt with it with
  - NAT
  - Name-based web hosting
  - Reallocation of network allocation & subnetting
- Those solutions helped a lot ... but not enough
  - We're out of IPv4 addresses in parts of the world
    - ARIN's free pool of IPv4 address space was depleted on September 24, 2015
  - IPv6 to the rescue!

CS 352 © 2013-2016 Paul Krzyzanowski 64

### Highlights

- Huge address space
  - 128-bit addresses:  $3.4 \times 10^{38}$  addresses ( $> 7.9 \times 10^{28}$  more than IPv4)
- Simplified 40-byte header
  - Longer addresses but far fewer fields
  - Focus is to simplify routing
- Anycast address
  - Allows a datagram to be delivered to one of a group of interfaces
  - Usually used to identify the nearest host of several hosts
- Flow label
  - Allows related packets that require specific levels of service to be identified
  - E.g., voice, video
  - Not well defined yet

### IP Datagram Structure

32 bits  
4 bytes

Version	Traffic class (8 bits)	Flow label (20 bits)
Payload length		Next header (8 bits) Hop limit (8 bits)
Source IP address (128 bits)		
Destination IP address (128 bits)		
Data		

40 bytes

CS 352 © 2013-2016 Paul Krzyzanowski 66

### IP datagram structure

- Version: protocol version = 6
- Traffic class: defines a category of service
- Flow label: identification tag for related flows
- Payload length: # bytes following the 40-byte datagram
- Next header: identifies higher-level protocol (e.g., TCP or UDP)
  - Same as in IPv4
  - Also permits extensions to IPv6, such as fragmentation, authentication
- Hop limit: TTL; decremented at each router
- Source & destination addresses
- Data
- No fragmentation – need to use IPv6 extension headers
  - Routers will never fragment IPv6 datagrams!
- No header checksum! Ethernet does it; so do TCP and UDP

## Transitioning

- IPv6 systems can bridge to IPv4 networks
  - IPv4 addresses are a subset of IPv6 addresses
- Dual-stack systems
  - Hosts with both IPv4 and IPv6 network stacks to communicate with both protocols
  - DNS can identify if a given domain is IPv6 capable or not
- IPv4 systems cannot communicate with IPv6 systems
  - Migrating to IPv6 results in a loss of global visibility in the IPv4 network
- Initial transition is not visible to end users
  - Cable modems, set-top boxes, VoIP MTAs
  - IPv6 access
