Explain the difference between confidentiality and integrity.

- · Confidentiality : restricts ability to read data
- Integrity : refers to the trustworthiness of the system & data
 restricts ability to modify data

CS 419 © 2017 Paul Krzyzanowsk

How do Linux capabilities help enforce the principle of least privilege?

- · Capabilities restrict what a process running as root can do.
- Unless a process <u>needs</u> specific controls (access to certain system calls), they can be disabled. That way, even if a process gets elevated privileges, it is limited in what it can do.

CS 419 © 2017 Paul Krzyza

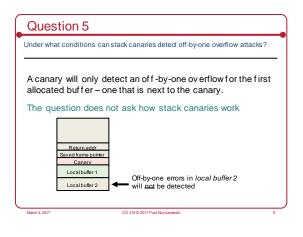

NOT: file protection

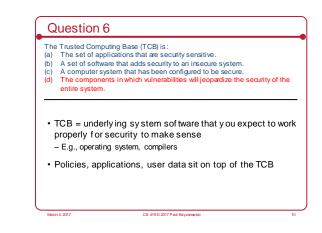

Question 4

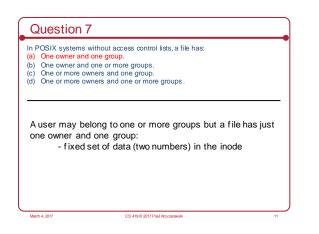

Why does the Biba model pose a risk to intellectual property theft?

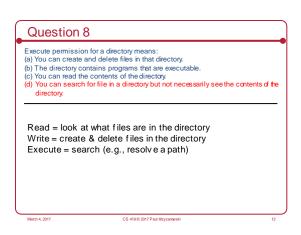

- Biba is not about confidentiality levels but integrity levels.
- A low integrity process can read high integrity data.
- When the same levels are used for confidentiality, a low integrity process can read high-value data even though it cannot modify it
- Example: Internet Explorer ran as a low integrity process so that malware would not be able to modify user or system files. However, that would not stop malware from reading that data (and possibly uploading it to a server)

An Access Control List (ACL) is:

- (a) A list of files and access permissions for a specific user.
- (b) A list of files that a user can access. A list of user and group access permissions for a file.
- (d) A list of users who are authorized to access the system.

An ACL is associated with a file Set of Access Control Entries: {user or group}: access permissions

Question 10

What is wrong here?

- program >secretfile; chmod u=rw,g=,o= secretfile (a) Group and other must be assigned some access permissions; they cannot have none.
- (b) There is a race condition that may allow an intruder to read secretfile
- (c) Another user with the same user ID will have access to the file. (d) A user cannot have both read and write access to the same file.

An intruder may open secretfile before the mode is changed.

CS 419 © 2017 Paul Krzyzano

Question 11

- Which activity violates the Principle of Least Privilege?
- (a) A mail server has access to all users' mailboxes (b) A print server can access a private spool directory.
- (c) A web server runs with root privileges to serve pages from user directories.
 (d) A user can collaborate with another user by editing the same file.

Principle of Least Privilege: don't give a process access to more than it needs to do its job

CS 419 © 2017 Paul Kzyzano

Question 12 Which operation is inefficient with capability lists? (a) Check the user's access permissions when opening a file. Copy file access rights of one user to another user. (b) (c) Change access rights of a single file for all use (d) Delete all access rights for a specific user. Access Control List: list of access permissions for different users - associated with a file Capability List: list of file access permissions for different files - associated with a user (a) Relatively easy: you'd expect to have this info cached for an active user (b) Super easy: copy a capability list from one user to another (c) A pain: have to search through all capability lists (d) Really easy: delete a user's capability list

CS 419 © 2017 Paul Krzyzanowski

Question 13

March 4, 2017

Mandatory Access Control (MAC) differs from Discretionary Access Control (DAC) because:

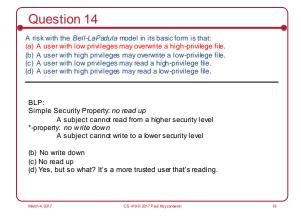

- (a) Users cannot change access permissions for their files.
 (b) MAC applies to subjects while DAC applies to objects.
- (c) MAC policies apply to a collection of computers while DAC policies apply to only one system.
- (d) The kernel enforces MAC permissions while DAC permissions are only advisory.

(a) DAC = users in control; MAC = admin in control

- (b) MAC & DAC both deal with how subjects are allowed to access objects
- (c) MAC or DAC don't say anything about a collection of computers that's up to OS admin controls

CS 419 © 2017 Paul Krzyzanowski

(d) The kernel always enforces access permissions - MAC or DAC

berh 4, 201

- Role-based Access Control (RBAC):
- (a) Allows file sharing only with users that have the same role.
- (b) Assigns hierarchical privilege levels to different classes of users in an organization.
- (c) Is a form of discretionary access control.
- (d) Is based on defining roles based on job functions.

 (a) Having *role* assigned to you does not necessarily give you file access for sharing: you might have the ability to add entries to a database, for example
 (b) RBAC does not have a concept of a hierarchy

(c) RBAC is mandatory access control – an admin assigns roles and access rules (d) Yes. The key point with RBAC is *roles* – a level of indirection between users and object permissions

Question 16

- What is the best way to prevent buffer overflow attacks?
- (a) Use a language that has run-time checks of array boundaries.(b) Address Space Layout Randomization.
- (b) Address Space Layout Randomiza(c) No-execute stack memory.
- (d) Stack canaries.

h 4, 2017

(a) Run-time checking ensures buffers will not overflow.

- (b) Buffers can still overflow it's just more challenging to find addresses
- (c) Buffers can overflow this led to return-to-libc and return-oriented-programming
- (d) Detects buffer overflow upon function return - Buffer overflow may be used before the *return* (e.g., other modified variables)
 - Builer overlidow may be used before the return (e.g., other modified variables)
 Exception handlers may be triggered to run injected code prior to the return
- Does not detect buffer overflows on the heap

Question 17

A landing zone is:

March 4, 2017

- (a) The current frame pointer, which defines the base for local variables.
- (b) A series of no-op instructions preceding injected code.
- (c) The buffer containing malicious code.
 (d) The location on the stack that contains the target branch address.

If you're not sure of the exact address of a buffer but have a general idea, a series of no-op instructions allow you to create a region into which execution can safely jump – and process no-ops until the useful injected code is reached.

Question 18 What will printf("%d%n", 123, &x) do? (a) Print "123" and write the pointer to the string "123" into x. (b) Print "123" and write the number 123 into x. (c) Print "123" and write the number 13 into x. (d) Print "123" and write the number 1 into x. %n writes the number of bytes output thus far into a specified memory location printf("%d", 123) will print "123" - 3 bytes so printf(%d%n", 123, &x) will write the value 3 to the address x

CS 419 © 2017 Paul Krzyzanowski

 Question 19

 Fuzzing is the technique of:

 (a) Using encrypted returm values on the stack so malicious code carnot write meaningful addresses.

 (b) Entering easy-to-find patterns to trigger buffer-overflow errors.

 (c) Having a compiler generate code to check for buffer overflows.

 (d) Exiting a program if a buffer overflow is detected.

 Testing technique:

 create a buffer overflow

 have the program crash

 search for the pattern

Question 21 With stack canaries, a compiler may reorder local variables such that: (a) Arrays and regular variables are randomly interspersed. (b) Arrays are allocated onto the heap and not the stack. Arrays are at the top of the stack, followed by regular variables (c) (d) Arrays are at the bottom of the stack, followed by regular variables. ar ar ar Undear answers - you will get credit for (c) or (d) To To To A compiler will try to allocate buffers first, followed by regular variables to disallow buffer overflows modifying local variables in the function Saved frame pointer Buffers scalars ints floats Top of stack

March 4, 2017

Question 22

SQL injection works when:

- (a) An attacker uses a buffer overflow exploit to change the query string.
- A buffer overflow exploit changes the operation of the SQL interpreter. User input becomes part of the query string. (b)
- (d) Executable code is sent as input instead of a query.

(a), (b); No need for buffer overflows

(d): You're not sending executable code (e.g., opcodes as you would in a buffer overflow attack) - just fragments of text that will change the syntax of the query

Question 23

- Setting the LD_PRELOAD shell variable:
- (a) Turns off Address Space Layout Randomization (ASLR), enabling attacks . (b) Preloads user input to a program.
- (c) Preloads a different program that will be executed whenever a user tries to run a program.
- (d) Allows you to overwrite library functions that a program might use

LD PRELOAD will force a library file to be loaded before any other library

When you run your program, it will check the pre-loaded functions first before checking other libraries

CS 419 © 2017 Paul Krzyzanor

Question 24

A homograph attack is a form of:

- (a) Deception Privilege elevation. (b)
- (c) Code injection.(d) Denial of service.

Deception:

A homograph attack creates words (usually domain names) that look the same but use different characters

CS 419 © 2017 Paul Krzyzanowski

h 4, 2017

Question 25 FreeBSD Jails are a big improvement over chroot because they: (a) Do not require root privilege to run. (b) Can limit the operations that a root user can perform in the jail.
 (c) Use a separate memory manager to ensure that jailed processes have their own address space (d) Create an isolated file system namespace.

Question 26

Social engineering refers to training individuals to follow proper security policies and be on the lookout for violations.

False.

It's about using deception to manipulate individuals

Data integrity means that the data can only be read by authorized users.

False.

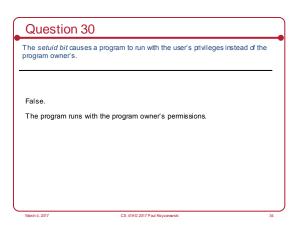

March 4, 201

It means only authorized users can modify data.

To avoid problems with pathnames referencing a file outside a base directory, you should reject any files that contain " \ldots /" substrings.

False.

Not good enough.

You'll end up rejecting valid names, such as "/whatever../index.html"

You'll also reject valid traversals within the allowable subtree:

/whatever/notes/../index.html

CS 419 © 2017 Paul Krzyzanavski

The Type Enforcement Model is essentially an admin-managed access control matrix.

True.

March 4, 201

It's an access control matrix (usually really restricted) that is processed before file $\ensuremath{\mathsf{ACLs}}$

CS 419 © 2017 Paul Krz

Question 34

The Chinese Wall Model relies on saving the state of past accesses.

True.

It has the concept of conflict dasses.

Based on what you accessed previously, you may not be allowed access to certain data.

| Question 35 | |
|--|--|
| A heap overflow cannot overwrite a return address. | |
| | |
| | |
| True. | |
| A return address sits on the stack. | |
| A heap overflow is not able to overwrite it. | |
| | |
| | |
| | |
| | |
| | |
