1

**Question 1**

What is a necessary condition for perfect secrecy?

Claude Shannon proved that a cipher has perfect secrecy **if and only if there are as many possible keys as possible plaintexts**, so every key is equally likely.

This means the key has to be **random** and **as long as the message** ... which means that this is not practical for most real-world use cases

See page 133 of the Security Engineering text.

2

**Question 2**

How did Robert Hooke use a one-way function in 1678?

He published an anagram of a message and revealed its meaning two years later.

This allowed him to establish priority for his idea (Hooke's Law for a spring) without disclosing it at the time.

See page 137 of the Security Engineering text.

3

**Question 2: Discussion**

This is a precursor to the idea of using a *hash*.

If I publish a hash of a message,  $H(M)$

... and later show you the message,  $M$ :

You know that I *must have had the message to generate that hash*

A good cryptographic hash function will make it difficult to generate a message that hashes to a specific, desired value

Note that "difficult" = "not feasible" = "impossible for all practical purposes"

4

**Question 3**

What are the three properties of hash functions listed in the text?

1. They are **one-way functions**
  - Given  $x$ , it is easy to compute  $h(x)$  but difficult to find  $x$  when given  $h(x)$
2. The function **does not give any information** about any part of the input.
3. It is hard to find **collisions**
  - A collision is when you can find two messages  $M_1, M_2$  where  $M_1 \neq M_2$  but  $h(M_1) = h(M_2)$

See section 5.3.1 (Random Functions – Hash Functions), 5.3.1.1 (Properties) Page 141

5

**Question 4**

What is meant by a trapdoor one-way permutation?

"This is a computation which anyone can perform, but which can be reversed only by someone who knows a trapdoor such as a secret key."

Public key cryptography is an example of this

- If I encrypt a message with my private key,  $k$ :  $C = E_k(M)$
- Nobody can decrypt it without the "trapdoor", knowledge of my public key,  $K$ :  $M = D_K(C)$

See page 147 of the text.

6

**Question 5**

How does *confusion* differ from *diffusion* in an SP network?

- **Confusion**
  - Confusion uses the key (known only to trusted parties) to modify the plaintext values (switch ones and zeros).
  - Every bit of ciphertext depends on various bits of the key. You cannot find a connection between a bit of the key and a bit of the ciphertext.
- **Diffusion**
  - The plaintext information is **spread** throughout the cipher so that a change in one bit of plaintext will affect many other bits
  - If you change a bit in the plaintext, approximately half of the bits in the ciphertext will change.

7

**Question 6**

What does an s-box do in a symmetric block cipher?

- It is a substitution box – it substitutes one pattern of bits with another
- Think of it as a lookup table
  - Example:
    - Input = 1101
    - Output = 1010

*See page 5.4.1, SP Networks, p. 149 in the Security Engineering text.*

8

6. Discussion: s-boxes

- **Block ciphers**
  - Encrypt a chunk of data at a time (rather than a byte at a time)
  - Versus **stream ciphers**, which encrypt one byte at a time
  - Essentially all symmetric block ciphers use SP Networks
- General goal: *Confusion and Diffusion*
  - *Confusion* = key hides the relationship between any bit of the plaintext input and any corresponding bit of the ciphertext output
  - *Diffusion* = spread plaintext data throughout ciphertext block
- **SP Networks: substitution and permutation**
  - Used in implementing block ciphers
  - **S-box** = lookup table that maps a set of bits onto another set
  - Some bits of the key may select which s-box to use
  - ... or some bits of the key might be used as input to the s-box

9

6. Discussion: s-boxes

- Encryption involves multiple rounds
  - The output of one set of s-box operations is used as input to the next round
- A simple 16-bit, 2-round SP-network from the text (p. 151):
